

## DESCRIPTION

## LINE LIGHT IRRADIATION DEVICE

## TECHNICAL FIELD

This invention relates to a lighting device for  
5 product inspection used for detecting flaws, recognizing a  
mark on a surface of a work or the like, more specifically a  
light irradiation device that irradiates line light.

## BACKGROUND ART

Conventionally, various lighting devices (light  
10 irradiation device) have been developed to carry out an  
inspection of a surface of a work. For example, an annular-  
shaped lighting device that irradiates light of a low angle  
from its circumference, a line-shaped lighting device that  
irradiates line light on a work, or other lighting device  
15 that meets various aspects of a work or various purposes of  
irradiating light have been known as the lighting devices as  
shown in Japan Patent laid open 1.

Especially, a line-shaped lighting device of a  
converging type is so arranged that bullet-shaped LEDs are  
20 laid out in a line and a cylindrical lens is arranged in  
front of the bullet-shaped LEDs so as to irradiate thin  
line-shaped light on a work.

Japan Patent laid open 1 number: 10-21729

## DISCLOSURE OF THE INVENTION

## 25 PROBLEMS TO BE RESOLVED BY THE INVENTION

However, the LEDs have a certain level of a light  
emitting area and can not be considered as a point light  
source. Then there is a problem that it is difficult to

gather rays of light so that enough lighting luminous intensity can not be obtained if a lens whose focal distance is short is used with an attempt to, for example, downsizing. On the one hand, if a lens whose focal distance is long is 5 used, it is possible to gather rays of light modestly. In this case, however, a size of the lens becomes extremely big, thereby to fail downsizing and being low in cost. Especially, if cylindrical lenses are arranged in multiple lines, a problem of a lens size becomes significant. As a result of 10 this, an arrangement in which multiple lines of line light each of whose three-dimensional angle differs can be gathered and irradiated has been less known.

As mentioned above, since light focusing efficiency (light use efficiency) and downsizing are in a trade-off 15 relationship for this type of a conventional line-shaped lighting device, an arrangement of the conventional line-shaped lighting device is low in design freedom and half-finished, resulting in difficulties to meet a requirement for lighting device. Furthermore, in case that multiple LEDs 20 are laid out in a line, a gap is formed between an LED and its adjacent LED from a viewpoint as a lighting source even though the LEDs are arranged thickly. As a result, there is a problem that unevenness of lighting is generated along a direction of the line.

25 The present claimed invention intends to solve the above-mentioned problems and its main object is to provide a line light irradiation device that is compact and that can improve light focusing efficiency without substantial

unevenness of lighting.

#### MEANS FOR SOLVING THE PROBLEMS

More specifically, the line light irradiation device in accordance with this invention comprises multiple light emitting parts each of which is provided with a light irradiating part where multiple optical fibers are thickly arranged in a line or in multiple lines with light leading out end portions of the multiple optical fibers forming a straight line of a predetermined width and a columnar lens arranged to extend along a direction of the line in front of the light irradiating part in pairs, and that irradiate line light that converges into a straight line, and a holding body that is arranged to face to a work as being an object on which the line light is to be irradiated, on which a monitoring bore is arranged to penetrate in order to monitor the work, and that holds the light emitting parts so that each optical axis face of the line light irradiated from each of the light emitting parts crosses on a predetermined straight line.

"Thickly" here is a state that each of the light leading out end portions is arranged with almost no space therebetween.

In order to make it possible to irradiate light of mutually different three-dimensional angle, it is preferable that each light emitting part is arranged on the holding body so that the optical axis face of the line light irradiated from each light emitting part is arranged radially viewed from the direction of the line.

As a more preferable embodiment for uniform lighting, it is preferable that the line light from each light emitting part is arranged side-by-side with no space therebetween so as to be the line light of continuous three-dimensional angle. In order to do so, it is preferable that each columnar lens is arranged generally on a straight line viewed from the direction of the line.

In order to hold multiple light leading out portions in a group easily, it is preferable that the light 10 irradiating part further comprises a pair of pinching plates and the pinching plates hold the light leading out end portions of the multiple optical fibers by pinching them.

As an arrangement to introduce light into each optical fiber effectively and uniformly, it is preferable that a 15 binding part is formed by binding each light introducing end portion of the optical fibers and light from a light source is introduced into the binding part.

Although the optical fiber itself is of flexibility that can be bent, it is very difficult for a band of the 20 optical fibers to inflect each optical fiber toward the direction of the line. As a result, if the band of the optical fibers is shaped to be, for example, axisymmetric to the center, the light sources have to be arranged lengthwise in case multiple light emitting parts are provided, thereby 25 failing to be downsized in a direction toward thickness.

With a view to solve this problem, in order to make it possible to mount the band of the optical fibers with ease even though multiple light sources are arranged along the

direction of the line on the holding body and to be downsized in the direction toward the thickness, it is preferable that the binging part is located to deviate to either one of directions with respect to a center line of 5 the light irradiating part.

As a concrete embodiment of the light source it is represented that the light source that introduces light into the optical fibers is a power LED that can continuously flow current greater than or equal to 200mA.

10 In order to make it possible to change a width of the irradiated line light so that various aspects of the light can be irradiated, it is preferable that a distance between the light irradiating part and the columnar lens can be varied.

15 In order to make it possible to set a position where the light is converged on the work in connection with a change of a distance between the work and the light emitting part, it is preferable that the light emitting part is rotatably around a rotational axis that is parallel to the 20 direction of the line and the rotational angle can be set.

In order to line up multiple types of the light irradiation devices that can irradiate line light whose length differs each other with suppressing a cost increase by standardizing basic components, it is preferable that the 25 multiple light irradiating parts are arranged serially along the direction of the line. This is because the length of the line light can be easily changed by changing a number of the serially arranged light irradiating parts.

Especially, in order to promote standardization of the basic components, it is preferable that each length of the light emitting part is identical (more preferably, the shape thereof is identical). On the contrary, with this 5 arrangement, the length of the line light is limited to a length that is integral multiplication of the length of the light irradiating part. In order to increase a number of variations of the length of the line light, it is preferable the light irradiating parts of several different lengths are 10 serially arranged. In spite of this, if too many variations are set for the length of the light irradiating part, an effectiveness of standardizing components is reduced.

In order to make an effect of reducing a cost more remarkable by standardizing the columnar lens also, it is 15 preferable that multiple light emitting parts of the identical length or of several different lengths are arranged serially.

In order to make it possible to reduce a burden on an image processing unit used in case of product inspection or 20 to flexibly meet other user requirement with realizing various types of light irradiation such as intensity of illumination is changed for each part of the line light by making use of the above-mentioned arrangement, it is preferable that the light source is arranged for each of the 25 light irradiating parts individually.

#### **ADVANTAGEOUS EFFECT OF THE INVENTION**

In accordance with the arrangement of this invention, since it is possible for the light irradiating part to

irradiate extremely fine line-shaped light, the line light that converges into extremely fine line-shaped light can be obtained even though the light emitting part is downsized by arranging the columnar lens whose focal distance is short

5 close to the light irradiating part. This arrangement makes it possible to provide varieties of light irradiating aspect by arranging multiple light emitting parts and to downsize each light irradiating part. In addition, it is possible to obtain the line light that ideally converges into a line-

10 shape and that is efficient in light focusing. In addition, since each of the light introducing out end portions is arranged thickly, the line light is free from unevenness, thereby enabling the lighting device that is high in evenness.

15

**BEST MODE FOR CARRING OUT THE INVENTION**

One embodiment of the present claimed invention will be described in detail with reference to the accompanying drawings.

20 A line light irradiation device 1 in accordance with this embodiment comprises, as shown in Fig. 1 through Fig. 4, multiple light emitting parts 2 that irradiate line light LL converging in a line shape and a casing 3 as being a holding body that holds the light emitting parts 2.

25 Each of the light emitting parts 2 is provided with a light irradiating part 21 where extremely fine (diameter of 0.25 mm in this embodiment) multiple optical fibers 4 are thickly arranged in a line or in multiple lines with its

light leading out end portion 4a arranged along a predetermined direction of the line P (shown in Fig. 5 and Fig. 6) and a rod lens 22 as being a columnar lens arranged to extend along the above-mentioned direction of the line P 5 in front of the light irradiating part 21 in pairs. Multiple light emitting parts 2 are arranged radially viewed from the direction of the line P.

The light irradiating part 21 further comprises, as shown in Fig. 5 through Fig. 7, a pair of plate-shaped 10 pinching plates 21a, 21b. The light irradiating part 21 has an arrangement that each of the light leading out end faces are arranged in several lines without a gap therebetween so as to draw a straight line of a predetermined width (about 0.25 mm through 1 mm) by pinching the light leading out end 15 portions 4a of the optical fibers 4 with the pinching plates 21a, 21b. Each of the rod lenses 22 is a three-dimensional cylindrical column transparent body with a cross-section of a circular form, and arranged so that each center axis of the rod lens 22 locates on an optical axis face T of light 20 irradiated from the light irradiating part 21.

The casing 3 is, as shown in Fig. 1 through Fig. 4, a hollow general cuboid body and a bottom face of the casing 3 is arranged to face to a work W as being an object on which the line light is to be irradiated. Strip-shaped monitoring 25 bores 3a, 3b are arranged to penetrate the top plate 31 and the bottom plate 32 of the casing 3 in order to monitor the work W.

Each of multiple (four in this embodiment) light

emitting parts 2 is mounted on the casing 3 in a state of being parallel each other through a fixing member 34 at a position facing to the monitoring bore 3b. Each of the light emitting parts 2 is arranged generally on a straight line

5 viewed from the direction of the line P and the optical axis face T of the line light LL irradiated from each of the light emitting parts 2 is arranged radially viewed from the direction of the line P. More concretely, it is so set that each optical axis face T of the line light LL irradiated

10 from each of the light emitting parts 2 crosses on a predetermined straight line and converges on the predetermined straight line. A measurement of a distance between the light emitting part 2 and its adjacent light emitting part 2 except for the light emitting parts 2

15 locating side-by-side on the center is so set that each line light LL is arranged to lie side-by-side with generally no gap therebetween and the generally continuous light of a three-dimensional angle is irradiated on the work W.

In addition, light sources 6 of the same number as

20 that of the light emitting parts 2 so as to correspond to each light emitting part 2 are mounted on a side plate 33 of the casing 3 through a bracket 35. Each of the light sources 6 comprises a single power LED (not shown in drawings), a lens mechanism (not shown in drawings) arranged in front of

25 the power LED, and a cylindrical body 61 that accommodates the power LED and the lens mechanism. In this embodiment the light sources 6 are mounted from outside on each of the side plates 33 two by two each of which is arranged side-by-side

along a direction of its depth. In order to mount each of the light sources 6, a light source mounting bore 35a that opens toward outside is arranged on the bracket 35. The light source 6 is detachably mounted by fittingly inserting 5 its light emitting end portion into the light source mounting bore 35a by the use of a setscrew B1. The power LED is an LED of a high luminance type that can continuously flow electric current greater than or equal to 200mA.

The optical fibers 4 are accommodated inside the 10 casing 3 and, as shown in Fig. 5 through Fig. 7, a binding part 41 is formed by thickly binding light introducing end portions 4b of the optical fibers 4 by the use of a cylindrical binding member 7 for each light emitting part 2 and the binding part 41 is mounted on a binding part 15 mounting bore 35b arranged on the bracket 35 from inner side of the binding part mounting bore 35b. More concretely, the binding member 7 is fittingly inserted into the binding part mounting bore 35b and detachably mounted on the binding part mounting bore 35b by the use of a setscrew B2.

20 One end of the binding part mounting bore 35b opens into an inner side of the bracket 35 and the other end of the binding part mounting bore 35b opens into a bottom of the light source mounting bore 35a. An axis of the binding part mounting bore 35b coincides with an axis of the light 25 source mounting bore 35a. The light source 6 is mounted on the light source mounting bore 35a and the binding member 7 is mounted on the binding part mounting bore 35b. With this arrangement, the light from the light source 6, namely the

light from the power LED is converged into a circular form whose diameter is the same as that of the binding part 41 and almost all of the light from the power LED can be introduced into each light introducing end face of the 5 optical fibers 4.

In this embodiment, as shown in Fig. 5 and Fig. 6, each length of all or a part of the optical fibers 4 is made to be different so that the binging part 41 is located to deviate to either one of directions in a plane view with 10 respect to a center line of the light irradiating part 21. The optical fiber 4 itself is elastic that can be bent, however, it is difficult for the bound optical fiber band 4A as noted above to bend to deviate the binding part 41 of the optical fiber 4 toward the direction of the line P. As a 15 result, with the arrangement of this embodiment wherein the light sources 6 are arranged along a direction of a depth (the direction of the line) P and each light source 6 is located to deviate from the center line of the light emitting part 2 in order to secure downsizing toward the 20 direction of the thickness, this shape that the binding part 41 has been deviated from the center line of the light emitting part 2 before is very effective. In this embodiment, four identical optical fiber bands 4A are formed and mounted two-by-two with its front and back sides turned upside down. 25

In accordance with thus arranged embodiment, since the light irradiating part 21 is so arranged that distal end portions of optical fibers 4 each of which can be considered as an extremely small point light emitting source are

thickly arranged in a line or in several lines and irradiates extremely fine line-shaped light, the irradiated light can be the line light LL that converges into extremely fine line-shaped light even though the irradiated light is gathered by arranging the rod lens 22 whose focal distance is short close to the light irradiating part 21. As a result, it is possible to obtain a lighting device that irradiates light ideally converging in line-shaped light and that is efficient in light focusing, in other words a luminous lighting device, as well as each light irradiating part 2 can be extremely downsized to be an arrangement that occupies little space.

In addition, since the light introducing out end portions 4a are arranged thickly, the line light LL is free from unevenness, thereby enabling to provide the lighting that is high in evenness. Furthermore, it is possible to utilize the rod lens 22 that is inexpensive, thereby to lower costs.

The present claimed invention is not limited to the embodiment.

For example, with the above-mentioned arrangement, in order to prepare several different types of lighting device that irradiates line light whose length differs, it is necessary to change a number of the optical fibers 4 and a length of the pinching plates 21a, 21b for each type of the lighting device

In this case, however, it is not possible to standardize basic components such as the optical fibers 4 or

the pinching plates 21a, 21b, thereby to diminish a size of a product lot or to increase a labor hour of manufacturing the product.

In order to solve this problem, this modified 5 embodiment is so arranged that the light emitting part 2 (the light irradiating part 21 and the columnar lens 22) of the identical length and of the identical shape is modularized to be one unit as shown in Fig. 8 and the multiple modularized units are arranged serially along the 10 direction of the line P. Furthermore, a single light source 6 is connected to each light emitting part 2, although not shown in drawings in this embodiment. It is a matter of course that a number of the optical fibers 4 and the shape 15 of the optical fiber band 4A to be connected to each light emitting part 2 are made to be identical.

In accordance with this arrangement, if a number of the serially arranged united light emitting parts 2 is changed, it is possible to prepare several different types of the light irradiation device that irradiates the line 20 light whose length differs and to promote standardization of components of the light irradiation device because the light emitting part 2 as being one of the basic components becomes a single type. As a result of this, a manufacturing cost can be reduced.

25 Furthermore, since the light intensity can be varied for each light emitting part 2, it is possible to irradiate not only the light of uniform intensity of illumination but also the light of a diversified range. As a result, various

effects can be obtained. For example, in case that the lighting device is used for conducting automatic inspection by taking a picture of the work W by a camera (not shown in drawings) through a monitoring bore 3a and by conducting an 5 image processing, an end portion of the image becomes dark due to a lens characteristic of the camera. With a conventional arrangement, this is corrected at a side of an image processing unit. With this arrangement, the S/N ratio is deteriorated due to a process of correction and time to 10 require image processing is necessary. On the contrary, in accordance with the arrangement of this embodiment, if the intensity of illumination at the end portion is made to be stronger than the intensity of illumination at the center portion, the process of correcting image conducted at the 15 side of the image processing unit can be decreased as much as possible. As a result, the S/N ratio can be maintained favorably and high-speed processing can be possible.

On the contrary, with the above-mentioned arrangement, a length of the line light is limited to a value of integral 20 multiplication of the length of the light irradiating part 21. In order to increase variations of the length of the line light, the light irradiating parts 21 of several (two through nine types) different lengths may be arranged 25 serially. However, if too many variations are set in order to be tailored to the length of the light irradiating part 21, an effectiveness of standardizing components is reduced.

In addition, since the columnar lens 22 can be made to be of various lengths only by a cutting process, only the

light irradiating part 21 is unitized and the columnar lens 22 is not necessarily unitized. However, if the light emitting part itself 2 is unitized like this embodiment, an effectiveness of modularization can be more remarkable.

5        In addition to this, there may be various modifications. For example, a half-mirror may be arranged above the monitoring bores 3a, 3b in a slanted posture so that the light is irradiated on the work W also through the monitoring bores 3a, 3b. Furthermore, the monitoring bores 10 3a, 3b may be blocked with a transparent member such as a glass plate so as to keep inside the casing 3 free of dust.

15      In addition, a distance between the light irradiating part and the columnar lens may be varied. In accordance with this arrangement, in case of adjusting each optical axis 15 face of the line light irradiated from each light emitting part, convenience is improved as well as a width of the line light irradiated on the work can be varied.

20      Alternatively, as shown in Fig. 9 and Fig. 10, the light emitting part 2 may be held by the casing 3 rotatably around a rotational axis that is parallel to the direction 25 of the line so that the light emitting part 2 can be set at an arbitrary angle or an angle of multiple steps within a certain range. In accordance with this arrangement, it is possible to set a position where the light converges on the work by adjusting the angle of each light emitting part according to a distance between the light emitting part and the work.

The rotational center is preferably on the center of

the axle of the columnar lens 22. This is because it is possible to restrain interference between each of the light emitting parts 2 due to a rotational movement as much as possible. As a concrete example as a rotational supporting structure of the columnar lens 22, a rotational axis 91 projects from the center of the end face of the columnar lens 22 toward an axial direction (direction of the line) and the rotational axis 91 is supported by a bearing 92 arranged on the casing 3. In addition, in order to change the angle, for example, a handle 93 may project from a rotational center X of the light emitting part 2 or a position deviating from the rotational center X toward the direction of the line so as to change the angle with an operation of the handle 93. Furthermore, in order to fix the angle, for example, a screw 94 may project inward from the casing 3 so as to fix the light emitting part 2 by pushing the end face of the light emitting part 2 with a distal end of the screw 92.

In addition, as mentioned above, in case of arranging the light emitting parts 2 (or the light irradiating parts 21) serially in multiple lines along the direction of the line, as shown in Fig. 9 and Fig. 10, a holding member 95 that holds whole light emitting parts 2 of one line may be arranged and the holding member 95 may be supported by the casing 3 with its rotational angle adjustable.

The columnar lens is not limited to the rod lens, and it may be, for example, a cylindrical lens of half-circle in a cross-sectional view, a Fresnel lens or the like. In

addition, as shown in Fig. 9 and Fig. 10, it may be provided with a mount aid part 22a such as a line-shaped convex or a groove extending from a side circumferential portion of the columnar lens 22 that is uninvolved with traveling of the

5 light along the axial direction and the columnar lens 22 may be supported by engaging the holding member 95 with the mount aid part 22a. In accordance with this arrangement, the columnar lens 22 can be held continuously from one end face to the other end face. Then this arrangement makes it

10 possible to hold the columnar lens 22 more securely by restraining bending or distortion of the columnar lens 22 in comparison with an arrangement where only an end portion of the columnar lens 22 is held.

Furthermore, a light homogenization member such as a

15 rod lens that homogenizes the light may be arranged between the light source and the binding part. In accordance with this arrangement, since the intensity of the light introduced into each optical fiber is made to be more equivalent, the unevenness of the intensity of illumination

20 of the line light can be more reduced. As another embodiment to reduce the unevenness of the intensity of illumination of the line light, it is conceived that a diffusion plate such as a lenticular lens is arranged between the light irradiating part and the columnar lens.

25 In addition, a color of the line light irradiated from each light emitting part may be varied each other or may be changeable.

It is a matter of course that the light source is

mounted on an appropriate position such as a top face of the holding body, furthermore the light source is not always mounted on the holding body. For example, the optical fiber may be elongated and the light source may be arranged 5 separately from the holding body. The number of the light source also is not limited to the above-embodiment and may be increased. The light source is not limited to the LEDs.

In addition, the light emitting parts may be arranged, for example, on a circular arc shape viewed from the 10 direction of the line.
